Random Vectors, Random Matrices, and Their Expected Values

Introduction

In order to decipher many discussions in multivariate texts, you need to be able to think about the algebra of variances and covariances in the context of random vectors and random matrices.

In this module, we extend our results on linear combinations of variables to *random vector* notation. The generalization is straightforward, and requires only a few adjustments to transfer our previous results.

Random Vectors

- A *random vector* ξ is a vector whose elements are random variables.
- One (informal) way of thinking of a random variable is that it is a process that generates numbers according to some law. An analogous way of thinking of a random vector is that it produces a vector of numbers according to some law.
- In a similar vein, a *random matrix* is a matrix whose elements are random variables.

Expected Value of a Random Vector or Matrix

- The expected value of a random vector (or matrix) is a vector (or matrix) whose elements are the expected values of the individual random variables that are the elements of the random vector.

Example (Expected Value of a Random Vector)

Suppose, for example, we have two random variables x and y, and their expected values are 0 and 2, respectively. If we put these variables into a vector ξ, it follows that

$$E(\xi) = E\left(\begin{bmatrix} x \\ y \end{bmatrix}\right) = \begin{bmatrix} E(x) \\ E(y) \end{bmatrix} = \begin{bmatrix} 0 \\ 2 \end{bmatrix}$$

Variance-Covariance Matrix of a Random Vector

Given a random vector $\boldsymbol{\xi}$ with expected value $\boldsymbol{\mu}$, the variance-covariance matrix $\boldsymbol{\Sigma}_{\xi\xi}$ is defined as

$$\begin{aligned} \boldsymbol{\Sigma}_{\xi\xi} &= E(\boldsymbol{\xi} - \boldsymbol{\mu})(\boldsymbol{\xi} - \boldsymbol{\mu})' \qquad (1) \\ &= E(\boldsymbol{\xi}\boldsymbol{\xi}') - \boldsymbol{\mu}\boldsymbol{\mu}' \qquad (2) \end{aligned}$$

If $\boldsymbol{\xi}$ is a deviation score random vector, then $\boldsymbol{\mu} = \mathbf{0}$, and

$$\boldsymbol{\Sigma}_{\xi\xi} = E(\boldsymbol{\xi}\boldsymbol{\xi}')$$

Comment

Let's "concretize" the preceding result a bit by giving an example with just two variables.

Example (Variance-Covariance Matrix)

Suppose

$$\boldsymbol{\xi} = \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

and

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}$$

Note that $\boldsymbol{\xi}$ contains random variables, while $\boldsymbol{\mu}$ contains constants. Computing $E(\boldsymbol{\xi}\boldsymbol{\xi}')$, we find

$$\begin{aligned} E\left(\boldsymbol{\xi}\boldsymbol{\xi}'\right) &= E\left(\begin{bmatrix} x_1 \\ x_2 \end{bmatrix}\begin{bmatrix} x_1 & x_2 \end{bmatrix}\right) \\ &= E\left(\begin{bmatrix} x_1^2 & x_1x_2 \\ x_2x_1 & x_2^2 \end{bmatrix}\right) \\ &= \begin{bmatrix} E(x_1^2) & E(x_1x_2) \\ E(x_2x_1) & E(x_2^2) \end{bmatrix} \end{aligned} \tag{3}$$

Comment

Example (Variance-Covariance Matrix [ctd.)

] In a similar vein, we find that

$$\begin{aligned} \boldsymbol{\mu}\boldsymbol{\mu}' &= \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix} \begin{bmatrix} \mu_1 & \mu_2 \end{bmatrix} \\ &= \begin{bmatrix} \mu_1^2 & \mu_1\mu_2 \\ \mu_2\mu_1 & \mu_2^2 \end{bmatrix} \end{aligned} \tag{4}$$

Subtracting Equation 4 from Equation 3, and recalling that $\text{Cov}(x_i, x_j) = E(x_i x_j) - E(x_i)E(x_j)$, we find

$$\begin{aligned} E(\boldsymbol{\xi}\boldsymbol{\xi}') - \boldsymbol{\mu}\boldsymbol{\mu}' &= \begin{bmatrix} E(x_1^2) - \mu_1^2 & E(x_1x_2) - \mu_1\mu_2 \\ E(x_2x_1) - \mu_2\mu_1 & E(x_2^2) - \mu_2^2 \end{bmatrix} \\ &= \begin{bmatrix} \sigma_1^2 & \sigma_{12} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix} \end{aligned}$$

Covariance Matrix of Two Random Vectors

Given two random vectors $\boldsymbol{\xi}$ and $\boldsymbol{\eta}$, their covariance matrix $\boldsymbol{\Sigma}_{\boldsymbol{\xi}\boldsymbol{\eta}}$ is defined as

$$\begin{aligned} \boldsymbol{\Sigma}_{\boldsymbol{\xi}\boldsymbol{\eta}} &= E\left(\boldsymbol{\xi}\boldsymbol{\eta}'\right) - E(\boldsymbol{\xi})E(\boldsymbol{\eta}') \qquad (5) \\ &= E\left(\boldsymbol{\xi}\boldsymbol{\eta}'\right) - E(\boldsymbol{\xi})E(\boldsymbol{\eta})' \qquad (6) \end{aligned}$$

Laws of Matrix Expected Value

Linear combinations on a random vector

- Earlier, we learned how to compute linear combinations of rows or columns of a matrix.
- Since data files usually organize variables in columns, we usually express linear combinations in the form $\mathbf{Y} = \mathbf{XB}$.
- When variables are in a random vector, they are in the rows of the vector (i.e., they are the elements of a column vector), so one linear combination is written $y = \mathbf{b}'\mathbf{x}$, and a set of linear combinations is written $\mathbf{y} = \mathbf{B}'\mathbf{x}$.

Laws of Matrix Expected Value

Expected Value of a Linear Combination

We now present some key results involving the "expected value algebra" of random matrices and vectors.

As a generalization of results we presented in scalar algebra, we find that, for a matrix of constants $\mathbf{B}$, and a random vector $\mathbf{x}$,

$$E\left(\mathbf{B}'\mathbf{x}\right) = \mathbf{B}'E(\mathbf{x}) = \mathbf{B}'\boldsymbol{\mu}$$

For random vectors $\mathbf{x}$ and $\mathbf{y}$, we find

$$E\left(\mathbf{x} + \mathbf{y}\right) = E(\mathbf{x}) + E(\mathbf{y})$$

Comment. The result obviously generalizes to the expected value of the difference of random vectors.

Laws of Matrix Expected Value

Matrix Expected Value Algebra

Some key implications of the preceding two results, which are especially useful for reducing matrix algebra expressions, are the following:

1. The expected value operator distributes over addition and/or subtraction of random vectors and matrices.
2. The parentheses of an expected value operator can be "moved through" multiplied matrices or vectors of constants from both the left and right of any term, until the first random vector or matrix is encountered.
3. $E(\mathbf{x}') = (E(\mathbf{x}))'$
4. For any vector of constants $\mathbf{a}$, $E(\mathbf{a}) = (a)$. Of course, the result generalizes to matrices.

An Example

Example (Expected Value Algebra)

As an example of expected value algebra for matrices, we reduce the following expression. Suppose the Greek letters are random vectors with zero expected value, and the matrices contain constants. Then

$$
\begin{aligned}
E\left(\mathbf{A}'\mathbf{B}'\eta\xi'\mathbf{C}\right) &= \mathbf{A}'\mathbf{B}'E\left(\eta\xi'\right)\mathbf{C} \\
&= \mathbf{A}'\mathbf{B}'\Sigma_{\eta\xi}\mathbf{C}
\end{aligned}
$$

Variances and Covariances for Linear Combinations

As a simple generalization of results we proved for sets of scores, we have the following very important results:

Given $\mathbf{x}$, a random vector with p variables, having variance-covariance matrix $\mathbf{\Sigma_{xx}}$. The variance-covariance matrix of any set of linear combinations $\mathbf{y} = \mathbf{B}'\mathbf{x}$ may be computed as

$$\mathbf{\Sigma_{yy}} = \mathbf{B}'\mathbf{\Sigma_{xx}}\mathbf{B} \tag{7}$$

In a similar manner, we may prove the following:

Given $\mathbf{x}$ and $\mathbf{y}$, two random vectors with p and q variables having covariance matrix $\mathbf{\Sigma_{xy}}$. The covariance matrix of any two sets of linear combinations $\mathbf{w} = \mathbf{B}'\mathbf{x}$ and $\mathbf{m} = \mathbf{C}'\mathbf{y}$ may be computed as

$$\mathbf{\Sigma_{wm}} = \mathbf{B}'\mathbf{\Sigma_{xy}}\mathbf{C} \tag{8}$$
